

$$\Pr[A \text{ breaks scheme}] \leq \underbrace{\text{Adv}_R(\text{hard primitive})}_{\text{negligible by assumption}} + \underbrace{\varepsilon_{\text{stat}}}_{\text{statistical error}}$$

security theorem: holds for all efficient probabilistic adversaries A

Key question: can every efficient A be *reduced* to breaking a hard primitive?

not “can the adversary derive this symbolic term?” (symbolic model)
but “does a PPT reduction R exist?” (computational / cryptographic model)
